Abstract: This paper is concerned with the Bohl-Perron theorem for differential algebraic equations. We prove that the system $E(t)x'(t) = A(t)x(t)$, $t \geq t_0$ is exponentially stable if and only if for any bounded input $q$, the equation

$$E(t)x'(t) = A(t)x(t) + q(t), \quad x(t_0) = 0, \quad t \geq t_0$$

has a bounded solution.

Keywords: Differential algebraic equation, asymptotic stability, input-output bounded function.

1. Introduction

In lots of applications there is a frequently arising question, namely how robust is a characteristic qualitative property of a system (e.g., the stability) when the system comes under the effect of uncertain perturbations. The designer wants to have operation systems working stably under small perturbation. Therefore, the investigation which conditions ensures robust stability play an important role both in theory and practice. On the other hand, to measure the robust stability, one proceed a test and expect that with rather good input, the output will satisfy some desired properties. For example, if the bounded input implies the boundedness of output then our system must be stable. The aim of this paper is to answer the above questions. We focus on studying the robust stability of time-varying systems of differential-algebraic equations (DAE-s) of the form

$$E(t)x'(t) = A(t)x(t), \quad t \geq t_0,$$  \hspace{1cm} (1.1)

where $E(\cdot), A(\cdot)$ are continuous matrix functions defined on $[0, \infty)$, valued in $\mathbb{R}^{d \times d}$. The leading term $E(t)$ is supposed to be singular for all $t \geq t_0$. If the system (1.1) is subjected to an outer force $q$, then it becomes

\[ E(t)x'(t) = A(t)x(t) + q(t), \quad t \geq t_0, \quad (1.2) \]

These systems occur in various applications, such as optimal control, electronic circuit simulation, multibody mechanics, etc., and they are described by a so-called differential algebraic systems with time varying, see [1, 2]. Therefore, it is worth to consider the stability such these system. To study that, the index notion, which plays a key role in the qualitative theory and in the numerical analysis of DAE-s, should be taken into consideration in the robust stability analysis, see [3, 4]. Many works are concerned to this problem such as [2, 5, 6]. In [7], Authors consider the Bohl-Perron type theorem for dynamic equation on time scales meanwhile in [8] Authors consider the stability under small perturbations for implicit difference equations. Our main goal of this paper is to develop these results by considering the relation between the stability of the system (1.1) and the analytic properties of outer force \( q(t) \).

The paper is organized as follows. In the next section we recall some basic notions and preliminary results on the theory of linear DAE-s and deal with the solvability of DAE-s. In Section 3, we prove that if the system (1.1) is exponentially stable, then under small feedback perturbations \( q(t) = B(t)x(t) \), the system (3.1) is still stable. In the last section, the famous Bohl-Perron theorem for linear equation is presented.

2. Preliminary

2.1. Some surveys on linear algebra

In this section, we survey some basic properties of linear algebra. Let \((E, A)\) be a pencil of matrices. Suppose that \( \text{rank} \ E = r \). Denote \( S = \{ x : \ A x \in \text{Im} \ E \} \) and let \( Q \) be a projector onto \( \text{Ker} \ E \).

**Lemma 2.1** The following assertions are equivalent

\[ a) \quad S \cap \text{Ker} \ E = \{ 0 \}; \quad \text{(2.1)} \]
\[ b) \quad \text{The matrix } \ G = E - AQ \text{ is nonsingular;} \quad \text{(2.2)} \]
\[ c) \quad \mathbb{R}^d = S \oplus \text{Ker} \ E; \quad \text{(2.3)} \]

**Proof** see [9, Appendix 1].

**Lemma 2.2** Suppose that the matrix \( G \) is nonsingular. Then, there hold the following relations:

\[ a) \quad P = G^{-1} E; \quad \text{where } \ P = I - Q. \]
\[ b) \quad -G^{-1} AQ = Q; \]
\[ c) \quad \tilde{Q} = -QG^{-1} A \text{ is the projector onto } \text{Ker} \ E \text{ along } S; \]
\[ d) \quad QG - I \text{ does not depend on the choice of } Q. \]

**Proof** See [9, Appendix 1].

2.2. Solvability of implicit linear dynamic equations

We consider the linear differential-algebraic system

\[ E(t)x'(t) = A(t)x(t) + q(t), \quad t \geq t_0, \quad (2.4) \]

where \( E, A \) are continuous matrix functions as in Section 1 and \( q \) is a continuous function defined on \([0, \infty)\), valued in \( \mathbb{R}^n \). Suppose that \( \text{Ker} \ E(t) \) is smooth in the sense there exists an continuously
differential projector $Q(t)$ onto $\text{Ker} \ E(t)$, i.e., $Q \in C^1(0, \infty, \mathbb{R}^{n \times n})$ and $Q^2 = Q$, $\text{Im} \ Q(t) = \text{Ker} \ E(t)$ for all $t \geq 0$. Set $P = I - Q$, then $P(t)$ is a projector along $\text{Ker} \ E(t)$. With these notations, the system (2.4) can be rewritten into the form

$$E(t)(Px)(t) = \tilde{A}(t)x(t) + q(t), \quad t \geq t_0,$$

(2.5)

where $\tilde{A} = A + EP$. Define $G = E - \tilde{A}Q$.

**Definition 2.3** (see also [6, Section 1.2]) The DAE (2.4) is said to be index-1 tractable if $G(t)$ is invertible for almost every $t \in [0, \infty)$.

Note that by Lemma 2, the index-1 property does not depend on the choice of the projectors $Q$, see [6, 5].

Now let (2.4) be index-1. Taking into account the equalities $G^{-1}E = P$, $G^{-1}A = -Q + G^{-1}AP$, and multiplying both sides of (2.2) with $PG^{-1}$, $QG^{-1}$ respectively, we obtain

$$\begin{align*}
(Px)' &= (P^* + PG^{-1}\tilde{A})Px + PG^{-1}q \\
Qx &= QG^{-1}\tilde{A}Px + QG^{-1}q.
\end{align*}$$

Thus, the system is decomposed into two parts: a differential part and an algebraic one. Hence, it is clear that we need only to address the initial value condition to the differential components. Denote $u = Px$, the differential part becomes

$$u' = (P^* + PG^{-1}\tilde{A})u + PG^{-1}q$$

(2.6)

Multiplying both sides of (3.3) with $Q$ yields $Qu' = QP'u = (Qu)' = Q(Qu)$. Hence, the equation (3.3) has the invariant property in the sense that every solution starting in $\text{Im} \ P(t_0)$ remains in $\text{Im} \ P(t)$ for all $t$.

We consider the homogeneous case $q(t) = 0$ and construct the Cauchy operator generated by (2.4). Let $\Phi_0(t, s)$ denote the Cauchy operator generated by the equation (3.3), i.e.,

$$\begin{align*}
\frac{d}{dt} \Phi_0(t, s) &= (P^* + PG^{-1}\tilde{A})\Phi_0(t, s) \\
\Phi_0(s, s) &= I.
\end{align*}$$

Then, the Cauchy operator generated by system (2.4) is defined by

$$\begin{align*}
E \frac{d}{dt} \Phi(t, s) &= A\Phi(t, s) \\
P(s)(\Phi(s, s) - I) &= 0
\end{align*}$$

and it can be given as follows:

$$\Phi(t, s) = (I + QG^{-1}\tilde{A})\Phi_0(t, s)P(s) = \tilde{P}(t)\Phi_0(t, s)P(s),$$

where $\tilde{Q}(t)$ is the canonical operator defined by (2.3) in Lemma 2 and $\tilde{P}(t) = I - \tilde{Q}(t)$ is a projector on $S(t)$ along $\tilde{Q}(t)$. By the arguments used in [6, Section 1.2], the unique solution of the initial value problem for (2.4) with the initial condition
\begin{align}
P(t_0)\left(x(t_0) - x_0\right) &= 0, \quad t \geq t_0, \\
\text{(2.7)}
\end{align}

can be given by the constant-variation formula

\begin{align}
x(t) &= \Phi_0(t, t_0)P(t_0)x_0 + \int_{t_0}^{t} \Phi(t, \rho)PG^{-1}q(\rho)d\rho + QG^{-1}q(t).
\end{align}

\text{(2.8)}

3. Stability under small perturbations

Consider the perturbation under the form \( q(t) = B(t)x(t) \) where \( B(t) \) is a matrix function. Then, the equation (2.4) becomes

\begin{align}
E(t)x'(t) = (A(t) + B(t))x(t), \quad t \geq t_0,
\end{align}

\text{(3.1)}

The equation (3.1) is an index -1 tractable if and only if the matrix \( \overline{G} = E - (A + B)Q \) is invertible. It is easy to see that \( \overline{G} = (I - BQG^{-1})G \). Therefore, the invertibility of \( G \) is equivalent to the invertibility of \( I - BQG^{-1} \). It is seen by Lemma 2 that the invertibility of \( I - BQG^{-1} \) does not depend on the choice of \( Q \).

**Definition 3.1**

1. The DAE (2.4) is said to be stable if for any \( \varepsilon > 0 \) and \( t_1 > t_0 \), there exists a positive constant \( \delta = \delta(\varepsilon) \) such that if \( \| \hat{P}(t_1)x_1 \| < \delta \) implies \( \| x(t) \| < \varepsilon \) for all \( t > t_1 \), where \( x(t) \) is the solution of (2.4) satisfying \( \| \hat{P}(t_1)(x(t_1) - x) \| = 0 \).

The DAE (2.4) is uniformly stable if it is stable and the above \( \delta \) is independent of \( t_1 \).

2. The DAE (2.4) is said to be exponential stable if there exist the positive numbers \( M > 0, \alpha > 0 \) such that

\begin{align}
\| x(t) \| \leq Me^{-\alpha(t-t_1)}\| \hat{P}(s)x(s) \|, \quad t \geq s, s, t \geq t_0.
\end{align}

Following the classical way, we see that exponential stability and uniformly stability of differential algebraic equation are characterized in term of its transition operator as the follows:

**Theorem 3.2**

1. The DAE (2.4) is uniformly stable if and only if there exist the positive numbers \( M_0 > 0 \) such that

\begin{align}
\| \Phi(t, s) \| \leq M_0, \quad t \geq s, t, s \geq t_0.
\end{align}

2. The DAE (2.4) is exponentially stable if and only if there exist the positive numbers \( M > 0, \alpha > 0 \) such that

\begin{align}
\| \Phi(t, s) \| \leq Me^{-\alpha(t-t_1)}, \quad t \geq s, \quad t, s \geq t_0.
\end{align}

\text{(3.2)}

**Proof** See [4].

For the uniform stability, we have the following result.
Theorem 3.3 Assume that the equation (2.4) is index-1, uniformly stable and satisfies

1. The matrices $I - \tilde{Q}(t)\tilde{G}^{-1}(t)B(t)$ are invertible $\forall t \geq t_0$ and

$$\sup_{t \geq t_0} \| I - \tilde{Q}(t)\tilde{G}^{-1}(t)B(t) \| = c < \infty.$$  

2. The integrals $\int_{t_0}^{\infty} \| \tilde{P}(t)\tilde{G}^{-1}(t)B(t) \| dt = N < \infty$.

Then, the system (3.1) is uniformly stable, i.e., there exists a constant $M_1 > 0$ such that the solution $x(\cdot)$ of (3.1) satisfies

$$\| x(t) \| \leq M_1 \| x(s) \|, \quad \forall t > s \geq t_0.$$  

Proof By using the constant-variation formula (2.8), for all $t > s \geq t_0$, we have

$$x(t) = \Phi(t,s)\tilde{P}(s)x_s + \int_s^t \Phi(t,s)\tilde{P}G^{-1}(s)x(s)\tilde{G}^{-1}(s)B(t)x(t)$$

$$\Rightarrow \left( I - \tilde{Q}\tilde{G}^{-1}(t)B(t) \right) x(t) = \Phi(t,s)\tilde{P}(s)x_s + \int_s^t \Phi(t,s)\tilde{P}G^{-1}(s)x(s)\tilde{G}^{-1}(s)B(t)x(t)$$

Therefore,

$$\| x(t) \| \leq \left\| I - \tilde{Q}\tilde{G}^{-1}(t)B(t) \right\| \left( \left\| \Phi(t,s)\tilde{P}(s)x_s \right\| + \left\| \int_s^t \Phi(t,s)\tilde{P}G^{-1}(s)x(s)\tilde{G}^{-1}(s)B(t)x(t) \right\| \right).$$  

(3.3)

By virtue of uniform stability of the equation (2.4), there exists the numbers $M_0 > 0$ such that

$$\sup_{t \geq t_0} \| \Phi(t,s)\tilde{P}(s) \| = \| \Phi(t,s) \| \leq M_0, \quad t \geq s \geq t_0.$$  

Since

$$\| x(t) \| \leq cM_0 \left\| x_s \right\| + cM_0 \int_s^t \| \tilde{P}G^{-1}(s)B(t) \| \| x(s) \| dt.$$  

By using Gronwall-Bellman inequality, we get

$$\| x(t) \| \leq cM_0 \exp \left\{ \int_s^t \| \tilde{P}G^{-1}(s)B(t) \| \| x(s) \| dt \right\} \leq cM_0 e^{N} \| x(s) \|.$$  

Put $M_1 = cM_0 e^{N}$, we obtain the proof. \(\square\)

Theorem 3.4 If the equation (2.4) is index-1, exponential stable and satisfies, the matrices $I - \tilde{Q}(t)\tilde{G}^{-1}(t)B(t)$ are invertible, $\forall t > t_0$ and

$$\sup_{t \geq t_0} \| I - \tilde{Q}(t)\tilde{G}^{-1}(t)B(t) \| = c < \infty,$$  

limsup$_{t \to \infty} \| \tilde{P}(t)\tilde{G}^{-1}(t)B(t) \| = \delta < \frac{\alpha}{cM},$

where $\alpha, M$ is defined by Definition 1. Then, there exist constants $K > 0$ and $\alpha_1$ such that

$$\| x(t) \| \leq Ke^{-\alpha_1(t-s)} \| x(s) \|, \quad \forall t \geq s \geq t_0.$$  

for every solution $x(\cdot)$ of (3.1). That is, the perturbed equation (3.1) preserves the exponential stability.
Proof. Let \( \varepsilon_0 \) be a positive number such that \( \varepsilon_0 < \frac{\alpha - \delta cM}{cM} \). Then, follow the second assumption, there exists \( T_0 > t \) such that
\[
\left\| \tilde{P}(t) \tilde{G}^{-1}(t) B(t) \right\| = \delta + \varepsilon_0, \quad \forall t > T_0.
\] (3.4)

By the continuity of the solutions of (3.1) on the initial condition we can find a constant \( M_{T_0} \) (where \( M_{T_0} \) depends only on \( T_0 \)) such that
\[
\| x(t) \| \leq M_{T_0} \| x(s) \|, \quad \text{for all} \quad t_0 \leq s \leq t \leq T_0.
\] (3.5)

First, we consider the case \( t > T_0 > s \geq t_0 \). Then, follow the estimations (3.3), (3.4) and (3.5), we get
\[
\| x(t) \| \leq \left\| \left( 1 - \tilde{Q} \tilde{G}^{-1} B(t) \right) \right\| \left\| \Phi(t, T_0) x_{T_0} \right\| + \int_{t_0}^{t} \left\| \Phi(t, \rho) \tilde{P} \tilde{G}^{-1} B(\rho) x(\rho) \right\| \| d \rho \|
\leq cM \left( e^{-\gamma(t-T_0)} \| x(T_0) \| + \int_{t_0}^{t} e^{-\gamma(t-\rho)} \| \tilde{P} \tilde{G}^{-1} B(\rho) \| x(\rho) \| \| d \rho \|ight.
\leq cM e^{-\gamma(t-T_0)} \| x(T_0) \| + cM (\delta + \varepsilon_0) \int_{t_0}^{t} e^{\gamma(\rho)} \| x(\rho) \| \| d \rho \|
\]
Multiplying both sides of the above inequality with \( e^{\alpha t} \) yields
\[
e^{\alpha t} \| x(t) \| \leq cMe^{\alpha T_0} \| x_{T_0} \| + cM (\delta + \varepsilon_0) \int_{t_0}^{t} e^{\alpha \rho} \| x(\rho) \| \| d \rho \|.
\]
By using Gronwall-Bellman inequality, we obtain
\[
\| x(t) \| \leq cMe^{\alpha T_0} \| x(T_0) \| e^{cM(\delta + \varepsilon_0)(t-T_0)}.
\]
Therefore,
\[
\| x(t) \| \leq cMe^{\alpha T_0} \| x(T_0) \| e^{cM(\delta + \varepsilon_0)(t-T_0)}.
\]
Paying attention on (3.5) obtains
\[
\| x(t) \| \leq cMe^{\alpha T_0} M_{T_0} \| x(s) \| e^{cM(\delta + \varepsilon_0)(t-T_0)}.
\]
Thus,
\[
\| x(t) \| \leq cMe^{\alpha T_0} M_{T_0} \| x(s) \| e^{-\alpha_1 (t-T_0)} = K_1 \| x(s) \| e^{-\alpha_1 (t-T_0)},
\]
where \( K_1 = cMe^{\alpha T_0} M_{T_0} \) and \( -\alpha_1 = cM (\delta + \varepsilon_0) - \alpha < 0 \).

In the case \( t > s \geq T_0 \), it follows from the estimate \( \left| \tilde{P}(t) \tilde{G}^{-1}(t) B(t) \right| \leq \delta + \varepsilon_0 \) holds for all \( \rho \geq s \). Similarly, we have
\[
\| x(t) \| \leq c \left( \int_{s}^{t} Me^{-\alpha_1 (t-\rho)} \| x(\rho) \| + \int_{s}^{t} Me^{-\alpha_1 (t-\rho)} \| \tilde{P} \tilde{G}^{-1} B(\rho) \| x(\rho) \| \| d \rho \right),
\]
and
\[ e^{\alpha t} \| x(t) \| \leq cM e^{\mu t} \| x(s) \| + cM (\delta + \varepsilon_0) \int_s^t e^{\alpha \rho} \| x(\rho) \| d\rho, \]

which implies
\[ e^{\alpha t} \| x(t) \| \leq cM e^{\mu t} \| x(s) \| e^{(\delta + \varepsilon_0)(t-s)} = cMe^{\delta(t-s)} \| x(s) \|. \]

For the remaining case \( t_0 \leq s \leq t \leq T_0 \), with \( \alpha_t > 0 \) defined above, we have
\[ \| x(t) \| \leq M_{\alpha_t} \| x(s) \| e^{\alpha(t-s)} \leq M_{\alpha_t} e^{\alpha(T_0-s)} \| x(s) \|. \]

Put \( K = \max \{ K_1, cM, M_{\alpha_t} e^{T_1} \} \), we get \( \| x(t) \| \leq Ke^{\alpha(t-s)} \| x(s) \|. \) The proof is completed. \( \square \)

4. Bohl-Perron Theorem for differential algebraic equations

The main aim of this section is to prove the Bohl-Perron’s Theorem for linear differential algebraic equation. That is we investigate the relation between the exponential stability of DAE (1.1) and the boundedness of solutions of nonhomogeneous equation (2.4).

In solving the equation (2.4) we see that the function \( q \) is split into two components \( PG^{-1}q \) and \( QG^{-1}q \). Therefore, we consider \( q \) as an element of
\[ L(t_0) = \left\{ q \in C([0, \infty], \mathbb{R}^d) : \sup_{t_0 \leq t} \| \tilde{Q}(t) \tilde{G}^{-1}(t)q(t) \| < \infty \text{ and } \sup_{t_0 \leq t} \| \tilde{P}(t) \tilde{G}^{-1}(t)q(t) \| < \infty \right\}. \]

It is easy to see that \( L(t_0) \) is a Banach space with the norm
\[ \| q \| = \sup_{t_0 \leq t} \| \tilde{Q}(t) \tilde{G}^{-1}(t)q(t) \| + \| \tilde{P}(t) \tilde{G}^{-1}(t)q(t) \|. \]

**Lemma 4.1** If for every function \( q(.) \in L(t_0) \), the solution \( x(., t_0) \) of the Cauchy problem (2.4) with the initial condition \( P(t_0)x(t_0) = 0 \) is bounded, then there is a constant \( k \) such that for all \( t \geq t_0 \),
\[ \sup_{t_0 \leq t} \| x(t, t_0) \| \leq k \| q \|. \] (4.1)

**Proof** By assumption, for any \( q(.) \in L(t_0) \), the solution \( x(t) \) associated to \( q \) of the Cauchy problem (2.4) with the initial condition \( P(t_0)x(t_0) = 0 \) is bounded on \([t_0, \infty)\). Therefore, if we define a family of operators \( \{ V_t \}_{t \geq t_0} \) as following:
\[ V_t : L(t_0) \to \mathbb{R}_d, \quad q \mapsto V_t(q) = x(t, t_0). \]

From the assumption of Lemma, we have \( \sup_{t \geq t_0} \| V_t(q) \| \leq \infty \) for any \( q \in L(t_0) \). Using Uniform Boundedness Principle, there exists a constant \( \tilde{k} > 0 \), independent of \( t \) such that
\[ \sup_{t \geq t_0} \| x(t, t_0) \| = k \| q \| \leq k \| q \| \] for all \( t \geq t_0 \).

The lemma is proved. \( \square \)
Lemma 4.2 Assume that the solution of the Cauchy problem (2.4) associated with every $q \in L(t_0)$ and the initial condition $P(t_0)x(t_0) = 0$ is bounded. Let $t_i \geq t_0$, then there exists a constant $k$ such that
\[ \sup_{t \geq t_i} \|x(t,t_i)\| \leq k \|q\| \text{ for all } t \geq t_i. \]
where $x(t,t_i)$ is the solution of (2.4) associated with $q \in L(t_i)$ and the initial condition $P(t_i)x(t_i) = 0$.

Proof Let $\tilde{q}$ be arbitrary function in $L(t_i)$. By variation of constants formula, the solution of the Cauchy problem (2.4) with the initial condition $P(t_i)x(t_i) = 0$ corresponding to $\tilde{q}$ is of the form
\[ x(t,t_i) = \int_{t_i}^t \Phi(t,\rho)\tilde{P}\tilde{G}^{-1}\tilde{q}(\rho)d\rho + \tilde{Q}\tilde{G}^{-1}\tilde{q}(t). \] (4.2)

Define $\tilde{q}$ in $L(t_i)$ as follow: if $t < t_i$, then $\tilde{q}(t) = 0$, else $\tilde{q}(t) = \tilde{q}(t)$. It is easy to see that the function $z(t) = x(t,t_i)$ if $t \geq t_i$, $z(t) = 0$ if $t < t_i$,
is the solution of the Cauchy problem (2.4) associated with $q = \tilde{q}$ and initial condition $P(t_i)x(t_i) = 0$.

By Lemma 3,
\[ \sup_{t \geq t_0} \|x(t,t_i)\| = \sup_{t \geq t_0} \|z(t)\| \leq k \|\tilde{q}\| - k \|\tilde{q}\|. \]
The proof is complete. \qed

Theorem 4.3 All the solutions of the Cauchy problem (2.4) with the initial condition $P(t_0)x(t_0) = 0$, associated with an arbitrary $q \in L(t_0)$ are bounded, if and only if the index-1 DAE (1.1) is exponentially stable.

Proof The proof contains two parts.

Necessity. First, we prove that if all the solutions of the equation (2.4) with the initial condition $P(t_0)x(t_0) = 0$, associated with $q \in L(t_0)$, are bounded then the DAE (1.1) is exponentially stable.

With an arbitrary $t_i \geq t_0$, let $\chi(t) = \|\Phi(t,t_i)a\|$, $t \geq t_i$ and $t \geq x_i \in \mathbb{R}^d$ such that $P(t_i)x(t_i) = 0$. Then, for any $a \in \mathbb{R}^d$, we consider the function
\[ q(t) = \frac{E(t)\Phi(t,t_i)a}{\chi(t)}, t \geq t_i. \]

It is obvious that
\[ \|\tilde{P}(t)\tilde{G}^{-1}(t)q(t)\| = \|\tilde{P}(t)\tilde{G}^{-1}(t)\frac{E(t)\Phi(t,t_i)a}{\chi(t)}\| \leq \|q\|. \]
\[ \|\tilde{Q}(t)\tilde{G}^{-1}(t)q(t)\| = \|\tilde{Q}(t)\tilde{G}^{-1}(t)\frac{E(t)\Phi(t,t_i)a}{\chi(t)}\| = 0. \]
Thus, $q \in L(t_0)$ and $\|q\| = \sup_{t \geq t_0} \left\{ \|\tilde{Q}(t)\tilde{G}^{-1}(t)q(t)\| + \|\tilde{P}(t)\tilde{G}^{-1}(t)q(t)\| \right\} \leq \|a\|$. Moreover,
\[
x(t, t_0) = \Phi(t, t_0) \tilde{P}(t_0) x_{t_0} + \int_{t_0}^{t} \Phi(t, \tau) \tilde{P} \tilde{G}^{-1}(\tau) d \tau + \tilde{Q}(t) \tilde{G}^{-1}(t) \tilde{q}(t)
\]
\[
= \int_{t_0}^{t} \Phi(t, \tau) \left( \Phi(\tau, t_0) a \right) d \tau + \int_{t_0}^{t} \Phi(t, \tau) a \frac{d \tau}{\chi(\tau)} = \int_{t_0}^{t} \Phi(t, \tau) a d \tau .
\]

Put \( \Psi(t) = \int_{t_0}^{t} \frac{1}{\chi(t)} d \tau \), we have
\[
x(t) = \Phi(t, t_0) \Psi(t) a .
\] (4.3)

From Lemma 3, we obtain \( \| x(t) \| = \| \Phi(t, t_0) \Psi(t) a \| = \| \Phi(t, t_0) a \| \| \Psi(t) \| \leq k \| q \| \leq k \| a \| \), which implies \( \| \Phi(t, t_0) \| \leq \frac{k}{\Psi(t)} \). Thus,
\[
\Psi'(t) \geq \frac{\Psi(t)}{k} \quad \text{or} \quad \Psi(t) \leq k \Psi(t).
\]

Then, with a fixed number \( c \) such that \( c \geq t_0 \), we have \( \Psi(t) \leq \Psi(c) e^{\frac{1}{k} (t-c)} \). Therefore,
\[
\| \Phi(t, t_0) \| \leq \frac{k}{\Psi(c)} e^{\frac{1}{k} (t-c)} = \frac{ke}{\Psi(c)} e^{-\frac{1}{k} (t-c)} .
\]

Setting \( \alpha = \frac{1}{k} \), \( N_i = \frac{ke}{\Psi(c)} e^{-\frac{1}{k} (t-c)} \) and \( K_i = \max \left\{ N_i, \max_{t_i \in I_{t_0}} \left\| \Phi(t, t_i) \right\| \right\} \), we obtain the estimate
\[
\left\| \Phi(t, t_i) \right\| \leq K_i e^{-\alpha (t-t_i)} , \quad \text{for all} \quad t \geq t_i .
\]

**Sufficiency.** To complete the proof, we will show that if (1.1) is exponentially stable then all solutions of the Cauchy problem (2.4) with the initial condition \( P(t_0) x(t_0) = 0 \) are bounded. Let \( q \in L(t_0) \), suppose that \( \sup_{t \geq t_0} \left\| \tilde{P}(t) \tilde{G}^{-1}(t) q(t) \right\| = C_1 \) and \( \sup_{t \geq t_0} \left\| \tilde{Q}(t) \tilde{G}^{-1}(t) q(t) \right\| = C_2 \).

Using again the formula (2.8) we have
\[
\left\| x(t) \right\| \leq \int_{t_0}^{t} \left\| \Phi(t, \rho) e^{\alpha (t-\rho)} \tilde{P} \tilde{G}^{-1}(\rho) q(\rho) \right\| d \rho + \left\| \tilde{Q} \tilde{G}^{-1}(t) q(t) \right\| \leq MC_1 \left( 1 - e^{-\alpha (t-t_0)} \right) + C_2 .
\]

Thus, the solutions of (2.4) are bounded. The proof is complete. \( \square \)
