Abstract: This paper the role of Cu$^{2+}$ concentrations in luminescence quenching of Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles synthesized by co-precipitation method. The synthesized Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles were observed to have sphere morphology with a diameter of ~25 nm. The XRD patterns of the nanoparticles revealed the peaks that were to be crystalline tetragonal ZrO$_2$. The addition of Cu$^{2+}$ to the Eu$^{3+}$ doped ZrO$_2$ nanoparticles resulted in a significant suppress luminescence in Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles, which was attributed to the spectral overlap occurs between Cu$^{2+}$ absorption and Eu$^{3+}$ emission ($^5D_0 \rightarrow ^7F_2$ transition).

Keywords: Zirconia; luminescence; precipitation; quenching, nanoparticles.

1. Introduction

Zirconia (ZrO$_2$) nanoparticles have received considerable attention in optoelectronic materials because of its high refractive index, optical transparency, corrosion resistance, photothermal stability, high thermal expansion coefficient, low thermal conductivity, high thermomechanical resistance, and

catalysis [1, 2]. In addition, the stretching energy of ZrO$_2$ is very low that opens up the possibility of higher efficient luminescence of activator ions incorporated into host ZrO$_2$ matrix [3, 4]. While it is generally accepted that doping Eu $^{3+}$ and Er $^{3+}$ ions into ZrO$_2$ nanoparticles tailors the luminescence of ZrO$_2$ nanoparticles [5, 6]. An alternate approach to producing luminescence with tailoring the light emission capabilities is to manipulate the matrix to control energy transfer [7, 8]. Previous studies reported that luminescence quenching for Eu $^{3+}$ emission was obtained by doping Cu $^{2+}$ in ZnO [9] and glass matrix [10]. In particular, in our knowledge, there are no reports on the luminescence quenching for Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles. Therefore, this study proposes a report for suppressing luminescence in Eu $^{3+}$ emission ($^{5}D_{0} \rightarrow ^{7}F_{2}$ transition) by introducing Cu $^{2+}$ into ZrO$_2$ matrix. The microstructure and crystal structure of the Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles were characterized by X-ray diffraction (XRD, D8 Advance, Bruker) and field emission scanning electron microscopy (FE-SEM, JEOL, JSM−7600F, JEOL Techniques), respectively. Light emission of nanowire was also determined by photoluminescence spectrometer (NANO LOG spectrofluorometer, Horiba).

2. Experimental procedure

Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles were synthesized through a co-precipitation method, as follows: ZrOCl$_2$.8H$_2$O (99 % purity, Aldrich, Saint Louis, US), CuCl$_2$.2H$_2$O (99.9 %, Aldrich, Saint Louis, My), and CTAB (99.9 %, Merck) was dissolved in distilled water (DW) under vigorous stirring at 25 °C for 30 min to obtain A solution. Eu(NO$_3$)$_3$ were obtained by dissolving stoichiometric Eu$_2$O$_3$ (99 % purity, Aldrich) in dilute HNO$_3$ with vigorous stirring. Various amount (0, 1, 3, 5, 7, 10 and 15 % mol Cu $^{2+}$) were used in all the set of the experiments, whereas, the sample was prepared according to the above procedure with the fixed amount of 5 % mol Eu $^{3+}$. The reaction mixture was further stirred for 0.5 h at 80 °C and pH was adjusted to 11 by using aqueous ammonia solution (Duc Giang Chemicals, Hanoi, Vietnam). The resulting precipitates were washed three times and then dried at 600 °C for 2 h. The crystalline structures of the Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles were characterized by X-ray diffraction (XRD, D8 Advance, Bruker, Germany). The microstructure and chemical composition of the Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles were determined by field emission scanning electron microscopy (JEOL, JSM−7600F, JEOL Techniques, Tokyo, Japan) and energy dispersive X-ray spectroscopy (EDS, Gatan, UK). To investigate the absorption properties of Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles, spectra were recorded in the wavelength of 200 to 800 nm using UV-Vis spectroscopy (Cary 5000, Varian). Photoluminescence (PL) tests were performed to evaluate the optical properties of Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles. NANO LOG spectrofluorometer (Horiba, USA) equipped with 450 W Xe arc lamp and double excitation monochromators was used. The PL spectra were recorded automatically during the measurements.

3. Results and discussions

Figure 1 shows the typical XRD patterns of the Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles synthesized by co-precipitation with different Cu $^{2+}$ concentrations in the reaction solution. All the Eu $^{3+}$/Cu $^{2+}$ doped ZrO$_2$ nanoparticles showed several strong peaks at 2θ = 30.2°, 35.4°, 50.3°, 60.2°, and 62.7° associated with the (001), (200), (112), (121) and (202) plane of the crystalline tetragonal ZrO$_2$ (JCPDS 50-1089, (Fig 1 (b) - (e)). However, the Eu $^{3+}$ doped ZrO$_2$ nanoparticles synthesized without the addition of Cu $^{2+}$ showed peaks attributed to the crystalline tetragonal ZrO$_2$ structure (JCPDS (50-1089) with additional peak at 2θ ≈ 28.4° corresponded to the (-111) planes of the crystalline monoclonal ZrO$_2$ structure (JCPDS 37-1484), (Fig 1 (a)). These results indicate that the Eu $^{3+}$ doped
ZrO$_2$ nanoparticles synthesized with the addition of Cu$^{2+}$ via a co-precipitation method had the preferential formation of tetragonal phase. It is also can be seen that XRD patterns obtained for all of Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles do not reveal the presence of any phases related to europium and other copper species, suggesting the successful preparation of Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles.

The microstructures variation in Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles synthesized co-precipitation method with different concentrations of Cu$^{2+}$ in the solution was examined by FE-SEM as shown in Figs. 2 (a)–(b). The Eu$^{3+}$/Cu$^{2+}$ doped ZrO$_2$ nanoparticles synthesized with and without Cu$^{2+}$ dopants showed spheres nanoparticles with the diameter of ~25 nm.

The representative chemical composition of the Eu\(^{3+}\) / Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles was characterized by EDS, as shown in Figs. 3. It can be seen that peaks corresponding to the Cu and Eu elements were observed, indicating the presence of the Cu and Eu in the ZrO\(_2\). In addition, a calculated atomic concentration of the Cu and Eu incorporated into ZrO\(_2\) was ~ 3.6 \% and 2.4 \%, respectively, which would be suggested to the successful doping of Cu and Eu into the host ZrO\(_2\).

Figure 4 shows the UV-VIS absorption spectrum of Eu\(^{3+}\) / Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles synthesized by co-precipitation with different Cu\(^{2+}\) concentrations in the reaction solution (0-15 \%). The Eu\(^{3+}\) / Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles synthesized with 0 \% Cu in the reaction solution showed an absorption peak at ~ 250 nm, Fig. 4 (a). On the other hand, when a certain concentration of Cu\(^{2+}\) was doped, a broad absorption peak at ~ (250- 280) nm was observed attributing for the contributions of O\(^{2-}\) - Cu\(^{2+}\) charge transfer transitions on the ZrO\(_2\) with an additional broad peak at ~ (550 nm - 800 nm) was assigned to the \(^2E \rightarrow ^2T_2\) (d – d) transition of Cu\(^{2+}\), Fig. 4 (b) - (f) [11, 12].

Figure 5 shows the emission spectra of Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles with different Cu\(^{2+}\) concentrations in the reaction solution. All the Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles showed strong visible emission peaks appeared at about 590, 616, 650 and 700 nm and they can be attributed to the \(^{5}D_{0}→^{7}F_{1}\), \(^{5}D_{0}→^{7}F_{2}\), \(^{5}D_{0}→^{7}F_{3}\), \(^{5}D_{0}→^{7}F_{4}\) transitions within Eu\(^{3+}\) ion, respectively. However, it should be noted that the PL spectra of the Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles decreased with increasing Cu\(^{2+}\) concentrations. In particular, when the concentration of Cu\(^{2+}\) reach 10\%\, they reached the significant decreasing the PL intensities and then decreased completely with further increasing Cu\(^{2+}\) concentrations to 15\%. This significant decreasing PL was mainly attributed to the achievement of Cu\(^{2+}\) dopants in the Eu\(^{3+}\)/ZrO\(_2\) nanoparticles, which can be explained by considering the photo quenching effect. More specifically, a decreasing luminescent emission of Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles is due to the spectral overlap occurring between Cu\(^{2+}\) absorption and Eu\(^{3+}\) emission (\(^{5}D_{0}→^{7}F_{2}\) transition) [10, 13].

4. Conclusions

We herein demonstrated that the luminescence quenching of Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles could be obtained effectively by controlling the concentrations of Cu\(^{2+}\) dopants. In particular, the co-doped of Eu\(^{3+}\) and Cu\(^{2+}\) into ZrO\(_2\) allows to achieve the tetragonal phase of ZrO\(_2\). The Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles synthesized without Cu\(^{2+}\) dopants showed typically visible emission peaks of Eu\(^{3+}\). On the other hand, when a certain concentration of Cu\(^{2+}\) was doped, luminescence quenching Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles was achieved. This luminescence quenching of Eu\(^{3+}\)/Cu\(^{2+}\) doped ZrO\(_2\) nanoparticles was mainly attributed to the containing of Cu\(^{2+}\) in the nanoparticle which is a suppressing Eu\(^{3+}\) luminescence.
