

## CLEISOSTOMA FLAVESCENS – NEW ORCHID SPECIES FROM NORTHERN VIETNAM

Leonid V. Averyanov & Anna L. Averyanova

Komarov Botanical Institute, Russian Academy of Science

**Abstract.** *Cleisostoma flavescens* Aver. & Averyanova (Orchidaceae) discovered in limestone area of the northern Vietnam is described as a new species to science. It belongs to sect. *Cleisostoma* and has close relation to *Cleisostoma aspersum* (Rehb.f.) Garay and *C. discolor* Lindl.

Recent botanical explorations of limestone areas in the northern Vietnam outlined this region as a very important center of plant endemism rich in orchid species having very limited distribution. This rocky mountain area composed with ancient highly eroded Paleozoic and early Mesozoic limestone hold unique botanical refugium for numerous outstanding strictly endemic orchids. Among them such exciting recently discovered species having great horticultural potential as *Anoectochilus calcareus*, *Holcoglossum wangii*, *Paphiopedilum hangianum*, *P. helenae*, *P. henryanum*, *P. herrmannii*, *P. hiepii*, *P. tranlienianum*, *P. vietnamense*, *Renanthera citrina*, *R. vietnamensis* and many others (Averyanov, 1997, 1998, 2000, 2002 a,b; Averyanov, Averyanova, 2000; Averyanov, at al., 2000, 2001; Averyanov, Rice, 2002). Group of these orchid species includes also newly discovered yellow-flowering species of the genus *Cleisostoma* Blume - *Cleisostoma flavescens*, which represents new species for science. This orchid has close relation to *Cleisostoma aspersum* (Rehb.f.) Garay and *C. discolor* Lindl. It was found in the northern Vietnam during field works on description of vegetation in habitats of endemic Vietnamese Paphiopedilums. Description of this rare, probably endemic plant is presented below.

***Cleisostoma flavescens* Aver. & Averyanova, sp.nov.** (*Cleisostoma* sect. *Cleisostoma*). Type: Northern Vietnam, Tuyen Quang Province, Na Hang District, Xuan Tam Municipality, near Ban Cai village (22°29'N, 105°20'E). Primary broad-leaved evergreen dry forest on very steep slopes of highly eroded remnant limestone ridge at elev. 450-500 m a.s.l. Common epiphyte. 22 March 2001, P.K. Loc, N.X. Tam, L. Averyanov, HAL 240 (holotype: HN!; isotype: LE!). Fig. 1.

A speciebus proximis (*Cleisostoma aspersum* (Rehb.f.) Garay et *C. discolor* Lindl.) species nova foliorum apice bilobato rotundato-obtuso, floribus minoribus flaviscentibus, labelli structura et calli posteriori forma valde differt.

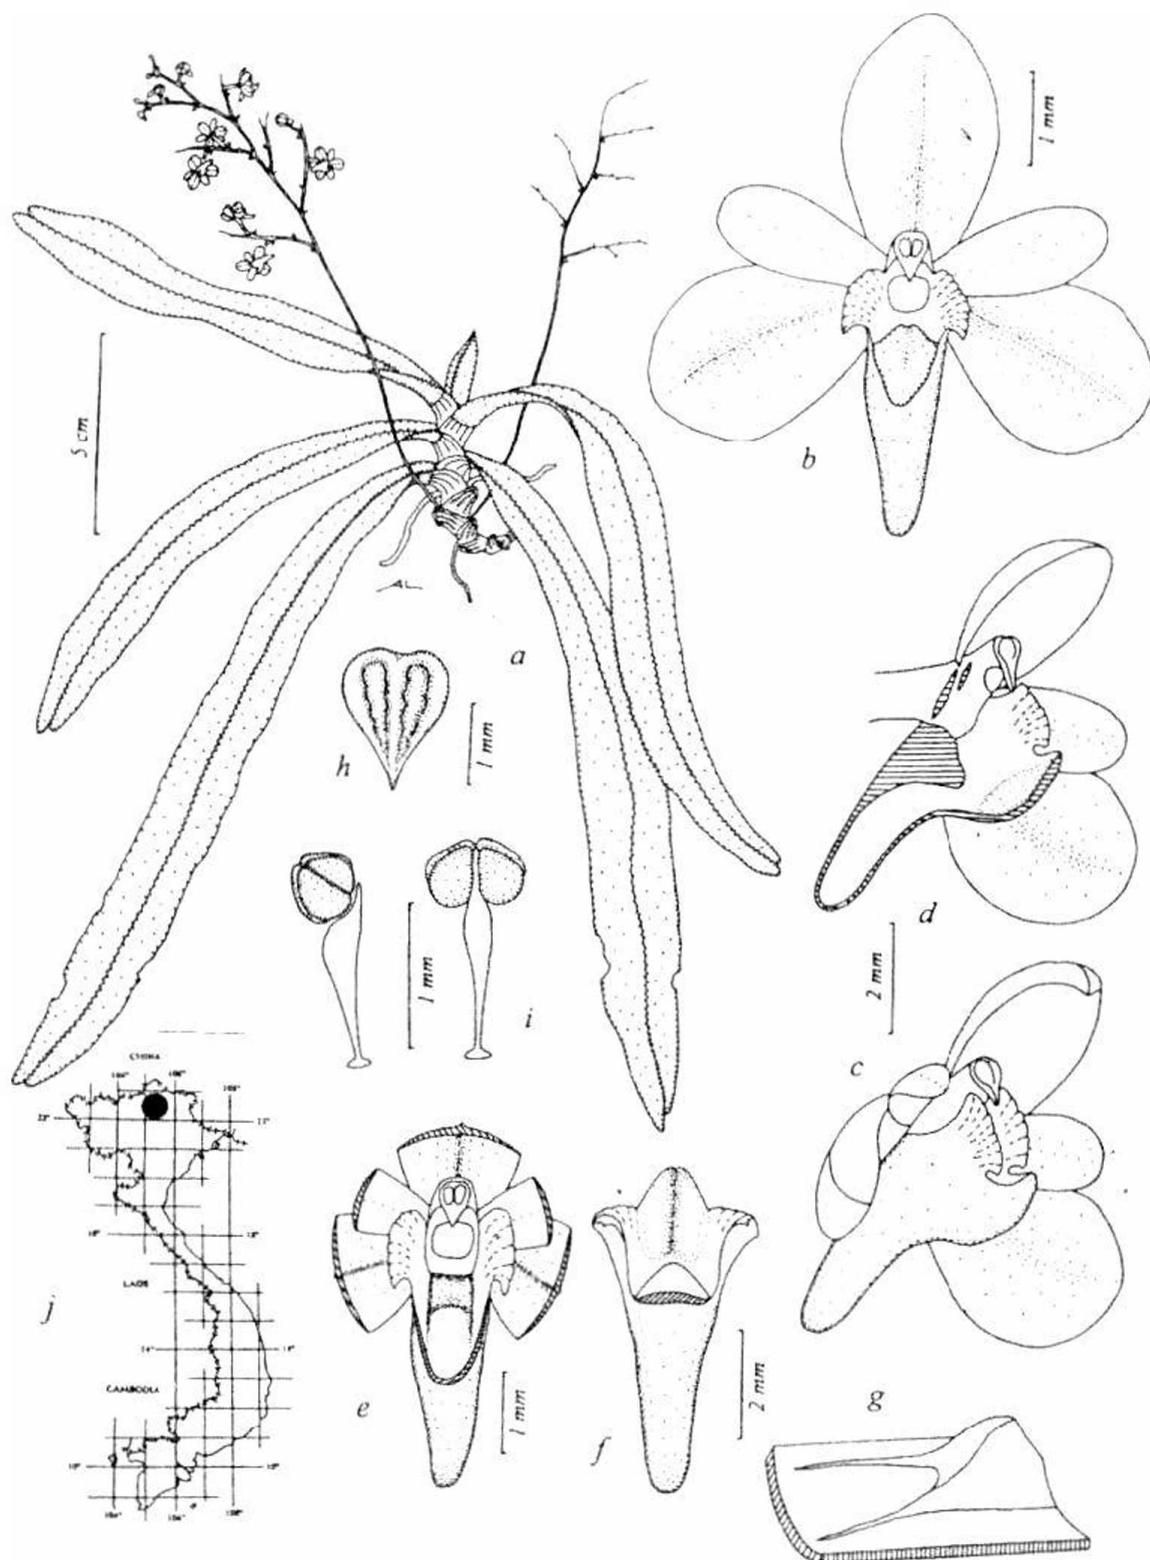

*Epiphyte* with roots about 2 mm wide, covered throughout with gray or whitish satiny velamen. *Stem* ascendant, suberect, curved at the base, rigid, about

4-6(12) cm long, 8 mm in diam., internodes about 0.7 cm long. Leaves usually 55-8.8-8, dorsiventral, coriaceous, up to 20 cm long and 2.1 cm wide, conduplicate with the distinct, prominent median vein, unequally bilobulate at the apex, with broad obtuse asymmetric lobes. Inflorescences lateral, 11-14(16) cm long, branched; scape and rachis thin, rigid, twig-like, deep green with purple or purple-violet tint. Inflorescence bracts ovate, about 4 mm long and 1.5 mm wide. Flower bracts small, oval, about 1 mm long and 0.5 mm wide. Pedicel and ovary 3-5 mm long, to 1 mm wide. Flowers odorless, tepals and lip light dull yellow, side lobes and apex of the lip white, column yellowish-white, anther cup dull yellow with few small purple marks near the apex; ovary dull yellowish-green with light indistinct purple tint. Dorsal sepal and petals curved forward, tepals except lip with indistinct purple median veins. Sepals obovate, about 3.8 mm long and 2.1 mm wide. Petals narrow lyrate, about 1 mm long and 1.5 mm wide. Lip about 6 mm from tip of mid-lobe to apex of spur. Spur cylindrical, slightly flattened from lateral sides, more or less straight, about 3 mm long and 1.4 mm at the widened base, the back-wall callus triangular in sagittal section, with two distal narrowing horns. Side lobes recurved, broadly truncate, finely denticulate at the edges. Mid-lobe fleshy, short, obtuse, acuminate, almost at right angle to the spur. Column about 1.5 mm high. Anther cup hemispherical, at front attenuate, dull light yellowish, with small indistinct purple marks. Pollinia 4 sub-equal, in two pairs.

**Etimology:** The name reflects dull pale-yellow color of flowers.

**Note.** *Cleisostoma flavescens* may be related to *Cleisostoma aspersum* (Rchb.f.f.f.) Garay and *C. discolor* Lindl., but distinguished by having broadly obtuse apical leaf lobes, in distinctly smaller dull pale yellowish flowers and in form of back-wall callus in the spur. This species was observed as locally common epiphyte in primary broad-leaved evergreen dry forest on very steep slopes of highly eroded remnant limestone ridge at elevation 450-500 m a.s.l. It flowered under cultivation in December-January. The species is local endemic of the northern Vietnam probably associated in its distribution with area of *Paphiopedilum hangianum*, *P. tranlienianum* and *P. vietnamense* (Fig. 1j).

**Acknowledgments.** The species was discovered during botanical exploration on expedition according to grant program of 100% Fund Fauna & Flora International (grant "The distribution of *Paphiopedilum vietnamense* and its current status in the wild"). We also would like to thank Mr. A.Sennikov for his kind correction of our use of the Latin language and Prof. Phan Ke Loc for final editing of the paper in the format of Vietnamese edition.

## CLEISOSTOMA FLAVESCENS - MỘT LOÀI LAN MỚI ĐỐI VỚI KHOA HỌC THU Ở BẮC VIỆT NAM

L.V. Avérianóp & A.L. Avérianóva

Viện thực vật học Cốmarov, Viện Hàn lâm khoa học Liên bang Nga

Trong bài báo đã mô tả một loài Lan (Orchidaceae) mới đối với khoa học thuộc tông *Cleisostoma* của chi *Cleisostoma* Blume, *Cleisostoma flavescens* Averyanov & Averyanova. Mẫu vật được P.K. Lộc, N.X. Tám và L. Avérianóp (số HAL 240, nơi lưu trữ: holotype: HN!; isotype: LE!) thu thập ngày 22 tháng 3 năm 2001 ở gần Bản Cái (22°29' B, 105°20' Đ) thuộc xã Xuân Tam, huyện Na Hang, tỉnh Tuyên Quang. Đây là loài Lan gặp khá phổ biến, sống bám trên cây gỗ, trong rừng nguyên sinh rậm rạp thường xanh cây lá rộng trên sườn núi đá vôi ở gần đỉnh và đường đỉnh, rất dốc và bị xói mòn mạnh, nơi có độ cao 450-500 m so với mặt biển. Loài Lan mới này rất gần gũi với 2 loài khác trong cùng chi là *Cleisostoma aspersum* (Rchb.f.) Garay and C. C. discolor Lindl. nhưng nó phân biệt bởi thuỷ của chóp lá tù rộng hay tròn, hoa màu vàng nhạt và nhỏ hơn rõ rệt và hình dạng của thể chai ở vách sau của hốc chứa mật. Cây nở hoa trong trồng trọt vào các tháng 12 và 1 năm sau. Đây là loài đặc hữu hè hép của bắc Việt Nam gặp trong vùng phân bố của một số loài Lan hài đặc hữu hèp như *Paphiopedilum hangianum*, *P. tranlienianum* và *P. vietnamense* (Fig. 1j).
