Abstract: In this paper, a finite element method (FEM) and a new third-order shear deformation plate theory are proposed to investigate a static bending model of auxetic plates with negative Poisson’s ratio. The three – layer sandwich plate is consisted of auxetic honeycombs core layer with negative Poisson’s ratio integrated, isotropic homogeneous materials at the top and bottom of surfaces. A displacement-based finite element formulation associated with a novel third-order shear deformation plate theory without any requirement of shear correction factors is thus developed. The results show the effects of geometrical parameters, boundary conditions, uniform transverse pressure on the static bending of auxetic plates with negative Poisson’s ratio. Numerical examples are solved, then compared with the published literatures to validate the feasibility and accuracy of proposed analysis method.

Keywords: Static bending; new third-order shear deformation plate theory; auxetic material.

1. Introduction

Auxetic materials are fascinating materials which, when placed under tension in one direction, become thicker in one or more perpendicular directions (Figure 1). In other words, an auxetic material possesses a negative value of Poisson’s ratio (Evans et al. [1]).

![Auxetic material](image)

Figure 1. Auxetic material [2].

Recently, numerous investigations on auxetic materials have been conducted by researchers in all over the world. The mechanical behaviors such as static bending, bucking load, dynamic response and vibration are studied a lot. Shariyat and Alipour [3] investigated bending and stress analysis of variable thickness FGM auxetic conical/cylindrical shells with general tractions (using first-order shear-deformation theory and ABAQUS finite element analysis code). The only published paper on stress analysis of the auxetic structures was due to Alipour and Shariyat [4] who developed analytical zigzag solutions with 3D elasticity corrections for bending and stress analysis of circular/annular composite sandwich plates with auxetic cores. Hou et al. [5] studied the bending and failure behaviour of polymorphic honeycomb topologies consisting of gradient variations of the horizontal rib length and cell internal across the surface of the cellular structures. The novel cores were used to manufacture sandwich beams subjected to three-point bending tests. Full-scale nonlinear Finite Element models were also developed to simulate the flexural and failure behaviour of the sandwich structures.

Auxetic plate and shell structures under blast load are mainly studied in nonlinear dynamic response and vibration problems. The calculus, semi-calculus, and numerical methods are proposed. There are a variety of studies applied analytical methods including the authors Duc and Cong [6-10]. In [6-10], the analytical Reddy’s (first or third) order shear deformation theory with the geometrical nonlinear in von Karman and Airy stress functions, Galerkin and the fourth-order Runge-Kutta methods were proposed to consider cell of honeycomb core layer (with NPR). Specifically, the nonlinear dynamic response of auxetic plate was conducted in [6], cylinder auxetic shell (within and without stiffeners) was illustrated in [7,10] and double curved shallow auxetic shells (without stiffeners) were mentioned in [8, 9].

From above literature review, in [3-5] the authors conducted bending and stress analysis auxetic structures using first-order shear strain theory and finite element method while in [6-10], an analytical method and (first or higher) order shear deformation theory were proposed to study dynamic response and vibration of auxetic plate and shell structures.

To the author’s best knowledge, a new third-order shear deformation plate theory has not been used in any published literature yet and it is also the main motivation of this research work. It introduces static bending analysis of auxetic plates with negative Poisson’s ratio using FEM and a new third-order shear deformation plate theory. The results show the effects of geometrical parameters, boundary conditions, uniform transverse pressure on the static bending of auxetic plates with negative Poisson’s ratio.

2. Sandwich plate with auxetic core

Considering a sandwich plate with auxetic core which has three layers in which the top and bottom outer skins are isotropic aluminum materials; the central layer has honeycomb structure using the same aluminum material (Figure 2a). The bottom outer skin thickness is \( h_1 \), internal honeycomb core material thickness is \( h_2 \) and top outer skin thickness is \( h_3 \), and the total thickness of the sandwich plate is \( h = h_1 + h_2 + h_3 \), as shown in Figure 2b.
The plate with the auxetic honeycomb core with negative Poisson’s ratio is introduced in this paper. Unit cells of core material discussed in the paper are shown in Figure 2c where $l$ is the length of the inclined cell rib, $h_c$ is the length of the vertical cell rib, $\theta$ is the inclined angle, $\alpha$ and $\beta$ define the relative cell wall length and the wall’s slenderness ratio, respectively, which are important parameters in honeycomb property.

\[
E_1^{(2)} = E \frac{n_3^3 (n_l - \sin \theta)}{\cos \theta^3 \left[ 1 + \left( \tan^2 \theta + n_l \sec^2 \theta \right) \eta_5^2 \right]}
\]
\[
E_2^{(2)} = E \frac{n_3^3}{\cos \theta (n_l - \sin \theta) \left( \tan^2 \theta + \eta_5^2 \right)}
\]
\[
G_{12}^{(2)} = E \frac{n_3^3}{\eta_l (1 + 2n_l) \cos \theta}
\]
\[
G_{23}^{(c)} = G \frac{n_3 \cos \theta}{h_l - \sin \theta}
\]
\[
G_{13}^{(2)} = G \frac{n_3}{2 \cos \theta} \left[ \frac{n_l - \sin \theta}{1 + 2n_l} + \frac{n_l + 2 \sin^2 \theta}{2(n_l - \sin \theta)} \right]
\]

where symbol “(2)” represents core material, $E, G$ and $\rho$ are Young’s moduli, shear moduli and mass density of the origin material.

3. New simple third-order shear deformation theory of plates

A finite element formulation based on a new third-order shear deformation plate theory, which is originally proposed by Shi in [12], for static bending analysis of auxetic plates is derived in this section. This new plate theory, in which the kinematic of displacements is derived from an elasticity formulation rather than the hypothesis of displacements, has shown more accurate than other higher-order shear deformation plate theories. The displacements,
$u$, $v$ and $w$ at any point of the plate are given by [12].

$$u = u_0 + \frac{5}{4} \left( z - \frac{4}{3h^2} z^3 \right) \phi_x + \left( \frac{1}{4} z - \frac{5}{3h^2} z^3 \right) w_{0,x}$$

$$v = v_0 + \frac{5}{4} \left( z - \frac{4}{3h^2} z^3 \right) \phi_y + \left( \frac{1}{4} z - \frac{5}{3h^2} z^3 \right) w_{0,y}$$

$$w = w_0$$

where $u_0$, $v_0$, and $w_0$ are respectively the displacements in the $x$, $y$ and $z$ directions of a point on the mid-plane of a plate, while $\phi_x$ and $\phi_y$ denote the transverse rotations of a mid-surface normal around the $x$ and $y$ axes, respectively.

Under small strain assumptions, the strain-displacement relations can be expressed as follows:

$$\begin{bmatrix}
\varepsilon_x \\
\varepsilon_y \\
\varepsilon_{xy} \\
\gamma_{yz} \\
\gamma_{xz}
\end{bmatrix} = \begin{bmatrix}
\varepsilon^{(0)} \\
\varepsilon^{(1)} \\
\varepsilon^{(2)} \\
0 \\
0
\end{bmatrix} + z \begin{bmatrix}
\varepsilon^{(1)} \\
0 \\
0 \\
0 \\
0
\end{bmatrix} + z^2 \begin{bmatrix}
0 \\
0 \\
0 \\
0 \\
0
\end{bmatrix}$$

(3)

Based on Hooke’s law, the vectors of normal and shear stresses read

$$\sigma^{(k)} = D^{(k)} \begin{bmatrix} \varepsilon^{(0)} + z \varepsilon^{(1)} + z^2 \varepsilon^{(3)} \end{bmatrix}$$

$$\tau^{(k)} = D^{(k)} \begin{bmatrix} \gamma^{(0)} + z \gamma^{(1)} + z^2 \gamma^{(2)} \end{bmatrix}$$

with

$$\sigma^{(k)} = \begin{bmatrix} \sigma_x^{(k)} & \sigma_y^{(k)} & \sigma_{xy}^{(k)} \end{bmatrix}^T$$

$$\tau^{(k)} = \begin{bmatrix} \tau_{yz}^{(k)} & \tau_{xz}^{(k)} \end{bmatrix}^T$$

$$D^{(k)} = \begin{bmatrix}
Q_{11}^{(k)} & Q_{12}^{(k)} & 0 \\
Q_{12}^{(k)} & Q_{22}^{(k)} & 0 \\
0 & 0 & Q_{66}^{(k)}
\end{bmatrix}$$
\[ D_s = \begin{bmatrix} Q_{55}^{(k)} & 0 \\ 0 & Q_{44}^{(k)} \end{bmatrix} \]  

(6)

\[ Q_{11}^{(2)} = \frac{E_1^{(2)}}{1-v_{12}^{(2)}V_{21}}, \quad Q_{12}^{(2)} = \frac{v_{12}^{(2)}E_2^{(2)}}{1-v_{12}^{(2)}V_{21}}, \]

\[ Q_{22}^{(2)} = \frac{E_2^{(2)}}{1-v_{12}^{(2)}V_{21}}, \quad Q_{66}^{(2)} = Q_{12}^{(2)}, \]

\[ Q_{44}^{(2)} = G_{23}^{(2)}, \quad Q_{55}^{(2)} = G_{13}^{(2)}, \]

\[ Q_{55}^{(1)} = \frac{\nu E}{1-\nu^2}, \quad Q_{11}^{(1)} = \frac{E}{1-\nu^2}, \]

\[ Q_{12}^{(1)} = \frac{\sqrt{E}}{1-\nu^2}, \quad Q_{11}^{(1)} = \frac{E}{1-\nu^2}. \]

The normal forces, bending moments, higher-order moments and shear force can then be computed through the following relations

\[ \bar{N} = \begin{pmatrix} N_x & N_y & N_{xy} \end{pmatrix}^T = \sum_{k=1}^{3} \bar{h}_{k+1} \int \begin{bmatrix} \sigma_x & \sigma_y & \sigma_{xy} \end{bmatrix}^T \, dz \]  

(7a)

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_m^{(k)} \left( \varepsilon^{(0)} + z \varepsilon^{(1)} + z^2 \varepsilon^{(3)} \right) \, dz \]

where

\[ (A, B, D, E, F, H) = \int_{-h/2}^{h/2} \left( 1, z, z^2, z^3, z^4, z^6 \right) D_m \, dz \]

\[ \bar{M} = \begin{pmatrix} M_x & M_y & M_{xy} \end{pmatrix}^T = \sum_{k=1}^{3} \bar{h}_{k+1} \int \begin{bmatrix} \sigma_x & \sigma_y & \sigma_{xy} \end{bmatrix} \, dz \]  

(7b)

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_m^{(k)} \left( \varepsilon^{(0)} + z \varepsilon^{(1)} + z^2 \varepsilon^{(3)} \right) \, dz \]

\[ \bar{P} = \begin{pmatrix} P_x & P_y & P_{xy} \end{pmatrix}^T = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_s^{(k)} \left( \gamma^{(0)} + z^2 \gamma^{(2)} \right) \, dz \]  

(7c)

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int \begin{bmatrix} \sigma_x & \sigma_y & \sigma_{xy} \end{bmatrix}^T \, dz \]

\[ \bar{Q} = \begin{pmatrix} Q_y & Q_x \end{pmatrix}^T \]

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_m^{(k)} \left( \varepsilon^{(0)} + z \varepsilon^{(1)} + z^2 \varepsilon^{(3)} \right) \, dz \]

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_s^{(k)} \left( \gamma^{(0)} + z^2 \gamma^{(2)} \right) \, dz \]

\[ \bar{R} = \begin{pmatrix} R_y & R_x \end{pmatrix}^T \]

\[ = \sum_{k=1}^{3} \bar{h}_{k+1} \int D_s^{(k)} \left( \gamma^{(0)} + z^2 \gamma^{(2)} \right) \, dz \]

Eqs. (7) can be rewritten in matrix form

\[ \begin{align*} 
\bar{N} &= \begin{bmatrix} A & B & E & 0 & 0 \\
B & D & F & 0 & 0 \\
0 & 0 & 0 & \bar{A} & \bar{B} \end{bmatrix} \begin{bmatrix} \varepsilon^{(0)} \\
\varepsilon^{(1)} \\
\varepsilon^{(3)} \end{bmatrix} \\
\bar{M} &= \begin{bmatrix} A & B & E & 0 & 0 \\
B & D & F & 0 & 0 \\
0 & 0 & 0 & \bar{A} & \bar{B} \end{bmatrix} \begin{bmatrix} \gamma^{(0)} \\
\gamma^{(1)} \\
\gamma^{(2)} \end{bmatrix} \\
\bar{P} &= \begin{bmatrix} A & B & E & 0 & 0 \\
B & D & F & 0 & 0 \\
0 & 0 & 0 & \bar{A} & \bar{B} \end{bmatrix} \begin{bmatrix} \varepsilon^{(0)} \\
\varepsilon^{(1)} \\
\varepsilon^{(3)} \end{bmatrix} \\
\bar{Q} &= \begin{bmatrix} A & B & E & 0 & 0 \\
B & D & F & 0 & 0 \\
0 & 0 & 0 & \bar{A} & \bar{B} \end{bmatrix} \begin{bmatrix} \gamma^{(0)} \\
\gamma^{(1)} \\
\gamma^{(2)} \end{bmatrix} \\
\bar{R} &= \begin{bmatrix} A & B & E & 0 & 0 \\
B & D & F & 0 & 0 \\
0 & 0 & 0 & \bar{A} & \bar{B} \end{bmatrix} \begin{bmatrix} \varepsilon^{(0)} \\
\varepsilon^{(1)} \\
\varepsilon^{(3)} \end{bmatrix} 
\end{align*} \]  

(8)
The deformation energy of auxetic plate has the form:

\[ U(d) = \frac{1}{2} \int_\Omega \left( \varepsilon^{(0)} A e^{(0)} + \varepsilon^{(0)} E e^{(3)} + \varepsilon^{(1)} T B e^{(1)} + \varepsilon^{(1)} T D e^{(1)} + \varepsilon^{(1)} T F e^{(3)} + \varepsilon^{(2)} T G e^{(2)} + \gamma^{(0)} T A f^{(0)} + \gamma^{(0)} T D f^{(2)} + \gamma^{(2)} T B f^{(0)} + \gamma^{(2)} T D f^{(2)} \right) d\Omega \]

(9)

For static bending analysis, the bending solutions can be obtained by solving the following equation:

\[ K d = F \]

(10)

where \( K \) is the stiffness matrix, \( F \) is force vector while \( d \) stands for the unknown vector.

4. Numerical results and discussion

Both the simply supported and fully clamped boundary conditions are investigated. For the simply supported boundary conditions (SSSS) [13]:

\[ u_0 = u = \phi_y = 0, \text{ at } x = 0, a \]
\[ u_0 = u = \phi_x = 0, \text{ at } y = 0, b \]

and the fully clamped edges (CCCC) [13]:

\[ u_0 = u_0 = u = \phi_x = \phi_y = 0 \]
\[ \partial w / \partial x = \partial w / \partial y = 0 \]

(11)

(12)

at \( x = 0, a \) and \( y = 0, b \)

In this section, the parameters are selected as: \( a = b = h = a / 20, h = 3 / 5 h, \)
\[ h_i = h / 5, E = 69 GPa, \nu = 0.3, \theta = 45^\circ, \]
\[ \eta_1 = 1.8, \eta_3 = 0.0138571. \]

4.1. Comparison with the results of the isotropic uniformity calculation

We consider a simply supported and clamped square plate (side \( a = 1 \)) under uniform transverse pressure \( ( F = 1 ) \), and thickness \( h \). The modulus of elasticity is taken \( E = 10,920 \) and the Poisson’s ratio is taken as \( \nu = 0.3 \). The non-dimensional transverse displacement is set as

\[ w = \frac{w}{D} \]

(13)

where the bending stiffness \( D \) is taken as

\[ D = \frac{Eh^3}{12(1 - \nu^2)} \]

(14)

The results compared with those of Ferreira [14] are shown in Table 1. In Ref. [14], the author used the theory of Mindlin plate considering for the Q4 element. From table 1, it can be seen a very small difference between 2 studies shows the reliability of the calculation program.

4.2. Static bending analysis of auxetic plate

The $20 \times 20$ Q4 mesh is used to measure static bending analysis of auxetic plate and $w$ is the deflection at position $x = 0.5m, y = 0.5m$.

To study the effect of the geometric parameters of the plate on the static bending of the auxetic sheet with a negative Poisson’s ratio, $b/a = 0.5, 1, 2.0$ and $b/a = 0.5, 1, 2.0$ are chosen. There are 9 different cases of auxetic plate structures considering 2 types of boundary conditions: SSSS and CCC. The results are illustrated in Table 2. Obviously, with different boundary conditions and the same value of $b/a$ the value of deflections $(w)$ decreases as the ratio $h/a$ increases (thicker plates) and vice versa. Whereas, in the case the same value of $h/a$, deflections’ value $(w)$ increase when increasing $b/a$ and vice versa.

Table 2. Effect of the ratio $(b/a)$ and on the deflections $(w)$ of the auxetic plate $(\nu_{21} = -0.646756)$

The analysis of the effect of \(l/h\) on the deflections \((\overline{w})\) of the auxetic plate consider different values of \(l/h=(0.2, 0.4, 0.6, 0.8, 1)\). From Table 3, the increasing in \(l/h\) leads to decrease in deflections \((\overline{w})\).

Figure 4. The deflections \((\overline{w})\) of auxetic plates.

Figure 4b shows deflections \((\overline{w})\) of the nodes in the diagonal direction of the plate as shown in Figure 4a. Figure 4 also illustrates that deflections have maximum values at the center of the plate and in the SSSS boundary condition, deflections are larger than those in the CCCC boundary condition.
Figure 5. Effect of uniform transverse pressure $F(P_a)$ on the deflections $\overline{w}$ of the auxetic plate ($v_{21} = -0.646756$)

The effect of uniform transverse pressure on the deflections $\overline{w}$ of the auxetic plate ($v_{21} = -0.646756$) is presented in Figure 5. It can be seen that increasing the value of uniform transverse pressure makes the value of deflections $\overline{w}$ and deformed shapes also increase (shown in Figure 6).

Figure 6. Deformed shape for simply-supported and clamped auxetic plates with value of uniform transverse pressure $F = 800 Pa$ and $v_{21} = -0.646756$. 
5. Conclusion

The paper successfully applied finite element method and a new third-order shear deformation plate theory to study static bending of auxetic plate. The calculation results are compared with other published paper validating the reliability of the calculation program. Then, effect of parameters on static bending of auxetic plates are examined in this paper.
